

Patent Instructions

As part of your project, you are required to submit a write up for a provisional patent. This will be a simple assignment as all you will need to do is write a few paragraphs about your project's concept and how your project works. All you need to do is to follow the directions as follows. We ask you a set of simple questions, and as long as you answer them you will hit the word minimum. Since this is a patent, speak formally. You may use the first person. You must refer to your project as your "invention" throughout the patent.

Name

The name of your provisional patent should be the name of your project, followed by a colon, then a small tagline to describe it. For example, for a project that manages a to-do list, its title would be "To-Do List: A Simple Yet Effective Method of Reminding People of Tasks to be Completed and Improving Everyday Life."

EES: Building a Better Understand of Player Reactions to Horror Stimuli

Background of the Invention (150 words)

What kind of framework does your project use (e.g. Flutter)? Who is your invention intended for (you can name multiple groups of people)? What kinds of problems does your intended audience face everyday? Explain how this is a big problem that affects their local communities as well. Your invention will improve their quality of life, by doing specifically what?

This invention is a first-person horror game and player-behavior study system built in Unity. The invention is intended for horror game players, student game developers, teachers, playtesters, and small game-design teams that want to understand why a horror experience feels tense, confusing, unfair, or exciting. Many horror games depend heavily on sudden jump scares, dark environments, or random enemy appearances, but these methods can make players feel lost instead of meaningfully scared. This creates a problem for both players and creators. Players may quit because they cannot understand the rules, while young developers may struggle to improve their levels because fear is difficult to measure. In a school or local game-development community, this makes it harder for students to learn strong design principles and build polished projects. This invention improves quality of life by making fear more readable and testable. It gives players clear goals, fair enemy rules, and a tense environment, while also giving the developer useful feedback about movement, deaths, pacing, and map design.

Summary of the Invention (150 words)

The significance of your invention is tied to the problem that it's trying to solve. State again the problem that your intended audience often faces. Specifically, how does your invention address

this? What are other products on the market that do something similar to your own? How does your invention improve on those other products? Highlight the main features of your invention and explain its benefits.

The problem addressed by this invention is that many horror games create fear in ways that are not balanced, measurable, or fair. A player may be scared, but the developer may not know whether the fear came from good atmosphere, confusing map design, enemy behavior, sound timing, or unfair key placement. This invention addresses that problem by combining a playable horror game with a structured feedback system. The invention places the player on a nighttime school campus, gives the player a clear objective of collecting keys, and requires the player to reach a safe zone while avoiding mannequins. Similar products include first-person survival horror games that use pursuit enemies, darkness, key collection, and jump scares. This invention improves on those products by making each threat rule-based and readable while also logging player paths, time spent in areas, and causes of death. Its main features include a Unity-built map, controlled key spawning, three mannequin enemy types, objective tracking, a locked safe zone, rising tension, and post-run behavior data. These features help create fear without relying only on randomness.

Detailed Description of the Invention (200 words)

Give a tour of your invention as if you were giving a demonstration of it. Start from your starting page. Then, explain any features of the app that the page utilizes (for example, a login screen, a post, a feed). How is a user supposed to interact with this screen? If there is another screen that is accessible, then move to that screen and repeat the process.

The invention begins with the player entering a single-player horror session set on a dark school campus. From the start, the invention shows a simple objective on the screen, such as finding all required keys before reaching the safe zone. The player experiences the invention from a first-person camera perspective and uses normal movement controls to walk, run, look around, and explore. The first area introduces the map, including outdoor paths, classrooms, hallways, corners, and dark spaces. These areas are designed to guide the player without obvious arrows. Narrow halls create pressure, open outdoor areas create exposure, and classrooms provide both possible safety and possible danger.

As the player explores, the objective system tracks the number of keys found. The invention spawns keys in selected locations so that each run can feel slightly different while still remaining fair. The player must search the campus, collect keys, and decide which routes are worth the risk. While this happens, the mannequin system creates the main danger. The invention includes three types of mannequins. One mannequin chases the player when it

detects them. Another moves only when the player is not watching it, creating tension through eye contact. A third mannequin hides or disguises itself until the player comes close, creating surprise without making the rule completely random.

When a mannequin catches the player, the invention can trigger a jump scare and end or reset the run. When all keys are collected, the safe-zone collider unlocks, and the player can escape by reaching the yellow safe area. During the session, the invention can record player paths, time spent in map zones, and death locations. This information helps the developer adjust lighting, sound, key placement, enemy speed, and patrol routes. Therefore, the invention functions as both a horror game and a design tool for creating fair, measurable fear.

Lastly, provide 2 screenshots of your invention.

Abstract of the Disclosure (100 words)

This is intended to be a short summary of everything you wrote. First, state the problem that your targeted audience often faces. Your solution is exactly what? What does your invention do? Highlight all its features. How does your invention solve this issue?

This invention solves the problem of horror games being difficult to balance because fear is often created through random jump scares, confusing spaces, or unclear enemy behavior. The invention is a Unity-based first-person horror game that studies player reactions to fear stimuli while remaining playable and fair. The player explores a nighttime school campus, collects keys, avoids three rule-based mannequin enemy types, and escapes through a safe zone. The invention includes a readable map, controlled key placement, objective tracking, rising tension, jump scares, and player-behavior logging. By recording movement, deaths, and pacing, the invention helps improve horror design through measurable feedback.
